

Alexey Grigorev

Tool calling is only one step

Production agents need an execution layer around the function call.

A schema is not a workflow

Tool calling means the agent can call a function with structured arguments. It does not answer what happens when the call fails.

The retry question

If a support ticket request times out, should the workflow retry? If the ticket was created, a blind retry can create a duplicate.

Production needs history

The workflow needs to know what was attempted, what failed, what returned, and whether retrying is safe.

Useful details to keep

Store per-step inputs, outputs, timeout state, retry count, recovery path, and idempotency information for side effects.

Workshop focus

We will look at state, retries, timeouts, recovery paths, human approval steps, and traces for production agent workflows.
