

Alexey Grigorev

Human approval is not just a button

When an agent waits for a person, the workflow needs durable state.

The diagram looks simple

The agent prepares an action. A person reviews it. The agent continues. That looks small in code.

Waiting changes the system

Approval can take two hours or two days. The worker can restart. A deploy can finish while the workflow is paused.

Approval needs storage

The workflow should write pending approval state, keep the workflow ID, and store the proposed action.

Resume from the event

When the approval event arrives, the workflow should continue from that step. It should not depend on one Python process still being alive.

Workshop focus

Nicholas Lotz will cover human-in-the-loop workflows, retries, timeouts, traces, recovery, and deployment patterns.

bring your approval workflow questions
