

Alexey Grigorev

When an agent fails, logs are not enough

You need to see the exact step, tool call, model call, timing, and retry path.

The wrong question

If the answer is wrong, saying the model did something weird does not help. You need to know which step changed the workflow.

Questions traces answer

Which tool was called? What arguments were sent? What came back? Was it a timeout, bad input, rate limit, or LLM decision?

What I would record

Run ID, step ID, prompt version, model response, tool name, tool arguments, tool response, latency, token usage, error, and retry count.

Debug before retrying

Before you retry or resume, you need to inspect what happened. Otherwise you are mostly reading logs and guessing.

Workshop focus

We will talk about the execution layer around agents: state, retries, recovery, human approvals, observability, and deployment.

join the observability discussion

Running Durable Agents in Production, June 16,
4:30-6:00 PM GMT+2 on YouTube.
