

Alexey Grigorev

Running Durable Agents in Production

A DataTalksClub workshop with Nicholas Lotz on June 16.

If you built a basic agent loop

You probably saw the next questions quickly: where to store state, how to recover, how to wait for approval, and how to debug failures.

Production needs the layer around the loop

The agent loop plans, calls tools, and returns answers. The production layer handles state, retries, recovery, approvals, traces, and deployment.

What we will cover

Why in-process loops fail, how to persist workflow state, resume after process death, retry tool calls, and handle approval steps.

What you will inspect

LLM calls, tool calls, timing, token usage, errors, retry attempts, and the execution history needed to understand a failed run.

Useful for real agent projects

This applies to RAG, workflow automation, data tasks, customer operations, internal tools, evaluation, monitoring, and production AI systems.
