

Alexey Grigorev

A practical agent workflow: PM, engineer, QA

Use roles, criteria, and loops to improve output quality.

PM grooms

The PM makes the issue concrete: goal, acceptance criteria, edge cases, and out-of-scope items.

Engineer implements

The engineer works from the groomed issue and commits the implementation.

QA verifies

QA checks each acceptance criterion. The verdict is pass or fail, with specific failures when needed.

Failures loop back

If QA fails the work, the issue returns to the engineer. The orchestrator keeps the workflow moving.

The trade-off

This uses more tokens than one prompt. The benefit is better quality because QA often catches missed behavior.
