

Alexey Grigorev

Agent observability starts with ingestion

Before dashboards, you need traces in a queryable destination.

Traces live in many places

They can come from local files, Logfire, Langfuse, platform APIs, internal loggers, or vendor APIs.

Each source has a shape

Tool calls, model usage, sessions, spans, inputs, outputs, and metadata may be represented differently.

The first job is ingestion

Collect traces, load them somewhere queryable, preserve the fields you need, and validate the resulting structure.

Then you can inspect behavior

Ask which models are used, which tools are called, which sessions fail, and where performance problems appear.
